CS470 Final Reflection

[Presentation](#)

During this course, I have learned what containerization is, and how it is implemented using Docker, and Docker Compose. It has taught me valuable knowledge in cloud computing, microservices, and serverless technologies. This information is important due to the growing demand for full-stack development and prepares me for roles in modern software development.

My strengths as a software engineer come from my ability to break down complex problems and translate them into code. I am always looking to optimize features at work and contribute to adding more value to projects. Upon completion of this course, I feel I have expanded upon my ability to launch and maintain full stack applications which directly impacts how I think and operate as an engineer.

With a handful of easy to use and streamlined microservices, using a serverless architecture can be useful to develop high efficiency web applications. Utilizing the serverless tools takes the load off myself, or team and allows focus to be honed on developing and architecting the actual application. A simple way to predict the cost of a pay-per-use model would be to estimate the general users need for your application and calculate that against how many users you expect to see use your service.

Elasticity is beneficial for future growth because at the core, means it can stretch and return to normal form. If traffic gets heavier, your application can expand its resources automatically using serverless architecture and the pay-per-use model allows for growth to match the need for instant scaling. You can avoid the worry and hassle of predicting needs and potentially over/underestimating the requirements and cost.
